Abstract: The purpose of this study was to investigate oestrus synchronization efficiency and ram maturity effect on fertility of ewes of MIS sheep population during summer season. Research was performed on the experimental sheep farm of the Institute for Animal Husbandry in Belgrade, Serbia. The study included 70 crossbred ewes of MIS sheep population (Pirot Pramenka, Merinolandschaf and Ile de France breed) and 3 Ile de France rams (2 young, sexually unexperienced rams and 1 mature ram). Oestrus was synchronized in all 70 ewes using progestagen impregnated vaginal sponges (30 mg fluorogestone acetate) in combination with 500 IU PMSG. Ewes were mated with rams 48 h later. Obtained fertility and productivity results were as follows: lambing rate 57.14% (40/70), gestation length 147.11, litter size 1.82, stillborn rate 15.07%, birth weight of lambs 4.29 kg and body weight of lambs at 30 days of age 13.07 kg on average. Based on the results obtained in this study it was concluded that presented oestrus synchronization and mating protocol yielded lower than expected lambing rate. The effect of ram maturity on lambing rate was significant (P<0.05), as ewes mated to mature ram had higher lambing rate compared to those mated to two young unexperienced rams. Mature ram also had bigger litter size and higher stillborn rate, as well as lower birth weight of lambs.

Key words: ram, maturity, fertility, oestrus synchronization, sheep

Introduction

The use of exogenous hormones for oestrus synchronization is a common practice in intensive sheep farming. Most commonly used procedure for oestrus induction/synchronization is application of progestagens via vaginal sponges in combination with PMSG or FSH, especially outside the breeding season. Progestagens are widely used to synchronize oestrus in sheep and usually result in greater than 90% of ewes in heat in a 24-hour period and conception rate of 70–
80% (Evans et al., 2001). However, fertility results achieved after hormone induced/synchronized oestrus vary depending on a number of factors, such as season, dose of PMSG used, fertilization method, body condition and physiology status of ewes. These are mostly female factors, but male factors, such as sperm fertility and libido, are also important. However, it is difficult to determine exactly which factors, female or male, contribute to fertility results and in what amount, but both must be taken into consideration.

MIS sheep population is a meat type breed of strong constitution, good carcass conformation and good meat quality properties. It was obtained by using a complex combination crossing according to a precisely defined genetic procedure, using Pirot Pramenka, Merinolandschaf and Ile de France breeds (Petrović, 2006). Ewes of MIS sheep population reach puberty at age of 6-8 months, which classifies them as the group of early maturing populations. In regard to fertility, MIS sheep population is very good if well managed and the use of progestagens in addition to PMSG hormone appears to be effective in the induction/synchronization of oestrus and in increasing of mean litter size outside the breeding season (Maksimović et al., 2015). However, there is not enough information in the literature on synchronization efficiency and fertility in ewes of MIS sheep population.

A significant percentage of domestic yearling rams are sexually inhibited when first exposed to oestrous ewes (Price et al., 1999b). Sexually inexperienced rams or ram lambs can often exhibit orientation problems with respect to mounting behavior. Among a group of oestrus ewes, rams can also show some preference for specific females while ignoring other ewes and this accounts for some differences in the lambing distribution (Fitzgerald and Morgan, 2007).

The role of experience on sexual performance suggests that early exposure to females will increase the probability of rams becoming sexually active at an earlier age (Perkins and Roselli, 2007). According to Perkins et al. (1992), the exposure of rams to oestrous ewes can increase the levels of LH and consequently the testosterone secretion in the ram, which in turn has been suggested to positively influence the production of pheromones (Haynes and Haresign, 1987). The close contact with ewes in oestrous also increases the libido of rams (Rodríguez Iglesias et al., 1991).

The purpose of this study was to investigate oestrus synchronization efficiency using progestagen+PMSG protocol and ram maturity effect on fertility in the ewes of MIS sheep population during summer season.

**Material and Methods**

*Location and animals*

Research was performed on the experimental sheep farm of the Institute for Animal Husbandry in Belgrade, Serbia at the end of July and the beginning of
August 2020. The study included 70 crossbred ewes of MIS sheep population (Pirot pramenka x Merinolandschaf x Ile de France) and 3 Ile de France rams. Ewes were 2 to 6 years of age, two young previously unexperienced rams (marked as ram 2 and ram 3) were both 1.5 year old and one mature ram (marked as ram 1) was 3 years old. Previous to mating, as well as after mating both rams and ewes were kept outdoors at pasture, but separately.

**Experimental design**

All 70 ewes were synchronized into oestrus using progestagen impregnated vaginal sponges (30 mg fluorogestone acetate, FGA, Syncro-Part, Ceva sante animale, France) in combination with pregnant mares serum gonadotropin (PMSG). Sponges remained *in situ* for 12 days. On the day of sponge removal, ewes received an intramuscular injection of 500 IU PMSG (Folligon®, MSD Animal health). Rams were introduced to ewes 48 hours later and were kept with them for mating for about 8-10 hours/day. Ram to ewe ratio for mating was 1:3/day. Mounting activities of rams were not recorded, neither visually or with harnesses (crayons). Ram breeding soundness was considered by inspection and examination or reproductive organs.

**The measured traits**

The following reproductive parameters were measured: lambing rate (number of ewes lambed/number of ewes mated), stillborn rate (number of stillborn lambs/number of lambs born), gestation length, litter size (number of lambs born/number of ewes lambed), birth weight of lambs, birth weight of lambs at 30 days of age.

**Statistical analysis**

Statistical analysis of the experimental data was performed using the statistical package Statistica for Windows 7 (Stat. Soft. Inc.). The equality of variances of analyzed treatments was tested using the Leven's test. Lambing rates and stillborn rates were tested by Chi square analysis. Effect of ram on litter size and birth weight of lambs was tested using ANOVA and the mean comparison between rams was done by Fisher’s LSD test. Analyses were performed for the significance level of 5% and 1% and the results were presented as mean±SEM.

**Results and Discussion**

Table 1 shows fertility traits (lambing rate, gestation length, litter size, stillborn rate) of ewes from synchronized oestrus and body weights of lambs at birth and 30 days of age.
Table 1. Fertility results of ewes and body weights of lambs (Mean±SEM)

<table>
<thead>
<tr>
<th></th>
<th>Lambing rate, %</th>
<th>Gestation length, days</th>
<th>Litter size (all lambs)</th>
<th>Litter size (live born only)</th>
<th>Stillborn rate, %</th>
<th>Birth weight of lambs, kg</th>
<th>Body weight of lambs at 30 days of age, kg</th>

Of the total of 70 ewes in the trial, 40 of them lambed after the synchronization of oestrus and joining with rams, representing lambing rate of 57.14%. Average gestation length was 147.11±0.14 days. Litter size was 1.82 lambs/ewe born (including stillborn lambs) and 1.55 lambs/ewe born including only live born lambs. Stillborn rate was 15.07%. Birth weight of lambs was 4.29±0.13 kg and body weight of lambs at 30 days of age was 13.07±0.46 kg on average. When compared to previous study of Maksimović et al. (2015) investigating the fertility of MIS sheep population after progestagen+PMSG synchronized oestrus outside breeding season, present study resulted in lower lambing rate, lower litter size, higher body weight of lambs at birth and at 30 days of age, as well as lower stillborn rate. Maksimović et al. (2017) also report higher lambing rate of 66.66% in MIS sheep population, although after repeated prostaglandin treatment for oestrus induction outside breeding season. Mekić et al. (2014) report lambing rates of 48.47% on average in Ile de France ewes after progestagen+PMSG oestrus synchronization protocol outside breeding season. Evans et al. (2001) state that the use of progestagen for oestrus synchronization typically results in greater than 90% of ewes in heat in a 24-hour period and conception rate of 70–80%. However, fertility results achieved after hormone induced/synchronized estrus vary depending on a number of factors, such as season, dose of PMSG used, fertilization method, body condition and physiology status of ewes. Also, male factors, such as sperm fertility and libido, are also important.

Table 2 shows effect of ram on lambing rate, litter size, stillborn rate and birth weight of lambs.

^A,B - Column means with different superscript letters differ significantly at P<0.01
As presented in Table 2, the effect of ram on all studied parameters was significant; 75% of ewes conceived and lambed with older, mature ram, compared to 47.83% of ewes that lambed after being mated to each of two young previously unexperienced rams (P<0.05). Mature ram also had bigger litter size and higher stillborn rate, as well as lower birth weight of lambs. Higher rates of stillbirths are common in more numerous litters, as well as lower birth weights are ([Berger, 1997; Maksimović et al., 2015]). With the use of exogenous hormones there is a greater chance for intense ovarian activity and ovulation of greater number of oocytes that will potentially be able to become fertilized. Highly prolific sheep breeds normally have higher mortality rates of lambs at birth compared to less fertile breeds, because of the more numerous litters ([Berger, 1997]).

It is common for young rams to give lower fertility results when first introduced to breeding. Price et al. (1994) point out that intermittent exposure of ram lambs to estrous ewes early in life can improve their sexual performance as yearlings. In later study, Price et al. (1999a) state that direct contact with females was necessary for enhanced sexual performance in young rams. Authors have found that 59% of the rams (age 7-8 months) reared without contact with females failed to become active during their first sexual performance test. In contrast, the same study showed that only 15% of the rams reared with direct contact with females were inactive during their first sexual performance test. Also, 38% of the rams that had fence-line contact with ewes was sexually inactive during their first test. High percentage of domestic yearling rams are sexually inhibited when first exposed to ewes in estrous, however, most of these rams will eventually mate with ewes after repeated or prolonged exposure to females ([Katz et al., 1988; Price et al., 1999b]). In the study of Price et al. (1999b), only 56% of tested rams successfully mated with estrous ewes on first exposure. Stellflug and Lewis (2007) conclude that early exposure of 7–8 months old ram lambs to oestrus ewes improves sexual performance in serving capacity tests at 16–19 months of age in most rams. However, some authors did not find clear link between maturity and previous experience of rams to fertility results in ewes. Kenyon et al. (2007) found that two-tooth rams previously unused and mature rams previously used for mating are a better option than unused ram hoggets to maximize the pregnancy rate of ewe hoggets, but that it was unclear why lower conception rates were observed in ewe hoggets joined with mature rams which had been used previously. Authors suggested that as a result, the advantage of using mature rams may have been underestimated.

With the practice of hand mating within restricted time it is ideal to have one on one ewe to ram ratio. When given a choice to choose between more females, rams tend to mate with same ewe/s more than once and not pay attention to others ([Tilbrook et al., 1987; Fitzgerald and Morgan, 2007], or they chase after all of them at once and become exhausted, which is common in first time breeders, or get intimidated by females, also common in young rams. Therefore, one ram to
three ewes ratio for limited time period mating that was used in this study could have contributed to less fertilized ewes and lower lambing rate.

However, it is difficult to determine exactly which factors, female or male, contributed to fertility results and in what amount, but both must be taken into consideration.

**Conclusion**

Based on the results obtained in this study it can be concluded that presented oestrus synchronization protocol of using progestagen+PMSG during summer months subsequently followed by mating of ewes through single natural service, yielded lower than expected lambing rate. Ram maturity had significant effect on lambing rate as ewes mated to mature ram had higher lambing rate compared to those mated to two young unexperienced rams. Mature ram also had bigger litter size and higher stillborn rate, as well as lower birth weight of lambs. Ram to ewe ratio of 1:3 may have also contributed to lower conception and lambing rate. Perhaps 1:1 to 1:2 ram to ewe ratio would be better when young rams are used for limited time breeding. Fertility results are influenced by both management and animals and therefore further studies are needed in order to determine what contributes the most. Also, modification of oestrus synchronization protocol and usage of different hormone levels to ensure better oestrus response for MIS sheep population can be considered. Use of teaser rams to detect ewes in heat and prolonged mating time could ensure higher conception rates. Also, concept of ram maturity and previous experience effect on mating abilities and fertility results should be further investigated.

Efekat sinhronizacije estrusa i uticaj zrelosti ovna na plodnost ovaca tokom letnje sezone

Nevena Maksimović, Dragana Ružić-Muslić, Violeta Caro Petrović, Violeta Mandić, Marina Lazarević, Bogdan Čekić, Ivan Ćosić

Rezime

Cilj istraživanja bio je da se ispita efikasnost sinhronizacije estrusa i uticaj zrelosti ovna na plodnost ovaca MIS populacije tokom letnje sezone. Ispitivanja su sprovedena na eksperimentalnoj farmi Instituta za stočarstvo u Beogradu, Srbija. U ogled je bilo uključeno 70 plotkinja MIS populacije (dobijene složenim kombinacijskim ukrštanjem pirotske pramenke, virtemberg i il de frans rase ovaca)
Oestrus synchronization efficiency in ewes and ram …

... and a reduction in disposability of eggs. Estrus is synchronized in all 70 ewes by the use of progestagens vaginal sponges (30 mg FGA) for 12 days and in combination with 500 i.j. SŽK. Plotkinje are allowed to be mated with rams 48 h after the administration of SŽK. The following results were obtained: pregnancy rate 57.14% (40/70), duration of pregnancy 147.11, pregnancy index 1.82, abortion rate 15.07%, birth weight 4.29 kg and birth weight in the age of 30 days 13.07 kg, average. The effect of age of ram on the pregnancy rate was statistically significant (P<0.05) where the plotkinje that were mated with mature rams showed a higher number of births in comparison to plotkinje that were mated with young, reproductively inexperienced rams. Mature ram also had a higher number of born lambs, a higher rate of abortions, as well as a lower birth weight.

Results of fertility are influenced simultaneously by the animals themselves and management in production, additional studies are needed to determine to what extent these factors contribute. The focus should be on eventual modification of estrus synchronization protocol to ensure a better estrus. The use of rams for estrus detection in ewes, as well as prolonging the duration of mating or double mating could ensure better pregnancy rate. In addition, it would be good to investigate the effect of age and previous reproductive experience of rams on parturition and fertility results.

**Ključne reči:** ovnovi, zrelost, plodnost, sinhronizacija estrusa
